

Project name: Checkpoint, A QR-based event RSVP and attendance management system

Problem statement

Organising academic seminars, expos and multi-day conferences often runs into three problems. Staff check attendees in by hand, which creates long queues at busy events. Paper or spreadsheet records miss people or double-count them. Organisers cannot track who visited each sub-activity, such as a booth or a workshop session, so they lose insight into which parts of the event people actually engaged with.

Objectives

- Automate verification: replace manual registration lists with a faster, error-free way to confirm each attendee's identity and entry.
- Diversify event workflows: support the different ways events run, from a single entry point to multi-day programmes to activities with several stops, so organisers are not stuck with one rigid check-in process.
- Provide real-time insights: give organisers live visibility into attendance and engagement, so they can act on the information immediately rather than after the event ends.
- Reduce administrative bottlenecks: cut the time each attendee spends at the check-in point, so queues move faster during high-capacity events.

Proposed solution

Checkpoint meets these objectives by automating attendance management using unique QR codes assigned to each registered attendee. The system verifies entry by scanning, tracks attendance across single-day, multi-day and booth-based events, and feeds all scan data into a live dashboard.

This gives organisers three benefits at once: faster entry queues, accurate attendance records with no manual counting, and a clear picture of engagement across every part of the event, from the main hall to individual booths.
